

The statistical model behind simmr (and SIAR)

Andrew Parnell
andrew.parnell@mu.ie

Learning outcomes:

- ▶ Understand the statistical model behind `simmr`/SIAR
- ▶ Know how to run a model in `simmr`/SIAR and check that it works
- ▶ Be able to follow the technical details of the 2010 SIAR Plos ONE paper

Our simple SIMM

- ▶ In the last class we had a simple SIMM defined via:

$$y_i \sim N\left(\sum_{k=1}^2 p_k s_k, \sigma^2\right)$$

with $s_k \sim N(\mu_{s_k}, \sigma_{s_k}^2)$, $p_1 \sim U(0, 1)$ and $\sigma \sim U(0, 100)$

- ▶ Here y_i is the isotope value, s are the source values, p are the dietary proportions, and σ is the residual standard deviation
- ▶ The goal is to estimate the p and its uncertainty. The other parameters can be considered nuisance parameters

Expanding the simple SIMM

- ▶ This SIMM is currently too simplistic. We need to expand it by:
 - ▶ increasing the number of food sources
 - ▶ including trophic enrichment factors (TEFs)
 - ▶ including concentration dependence
 - ▶ allowing for multiple isotopes
 - ▶ allowing for richer source sampling by consumers
- ▶ If we include all of these factors we end up with the `simmr`/SIAR model
- ▶ We will take them in turn and add them into our JAGS code

Reminder: the SIAR geese data

```
data(geese_data_day1)
str(geese_data_day1)
```

```
## List of 8
## $ mixtures          : num [1:9, 1:2] -11.4 -11.9 -10.6 -11.2 -11.7 ..

```

Plotting the data

A plot in isotope space:

```
plot(simmr_in)
```

Including multiple sources

- ▶ Adding in multiple sources to the likelihood means having more terms in the sum:

$$y_i \sim N \left(\sum_{k=1}^K p_k s_k, \sigma^2 \right)$$

- ▶ In the above we have K sources and hence K dietary proportions
- ▶ We also now need K source prior distributions
- ▶ The tricky part about adding in multiple proportions is the prior distribution

Priors for constrained dietary proportions

- ▶ We must have $\sum_{k=1}^K p_k = 1$ so any prior distribution we place on the p s must satisfy this restriction
- ▶ (You will often hear values restricted in sum referred to as a *simplex*)
- ▶ Luckily there is a distribution known as the *Dirichlet* which is suitable for restricted sum parameters
- ▶ The Dirichlet has one parameter for each proportion $\alpha_1, \dots, \alpha_K$. The larger the α value the larger prior weight that dietary proportion will be given
- ▶ Setting all the α values to 1 is equivalent to the simplex uniform distribution, i.e. a prior assumption that all sources are consumed equally

JAGS SIMM with a Dirichlet prior

```
model_code = '  
model {  
  for(i in 1:N) { y[i] ~ dnorm(inprod(p,s),sigma^-2) }  
  p ~ ddirch(alpha)  
  for(k in 1:K) { s[k] ~ dnorm(s_mean[k],s_sd[k]^-2) }  
  sigma ~ dunif(0,100)  
}  
,  
data=with(geese_data_day1,  
  list(y=mixtures[,1],  
       s_mean=source_means[,1],  
       s_sd=source_sds[,1],  
       N = nrow(mixtures),K=nrow(source_means),  
       alpha=rep(1,nrow(source_means))))  
set.seed(123)  
model_run = jags(data = data,  
  parameters.to.save = c("p", "sigma"),  
  model.file = textConnection(model_code))
```

Results

- ▶ We can explore/plot results with `summary(output)`, `plot(output)`, and also run multiple chains, form predictive distributions, check convergence, etc
- ▶ One important thing to note is that the fitting method (MCMC) produces a joint posterior distribution of the dietary proportions. This means that each set of samples will sum to 1:

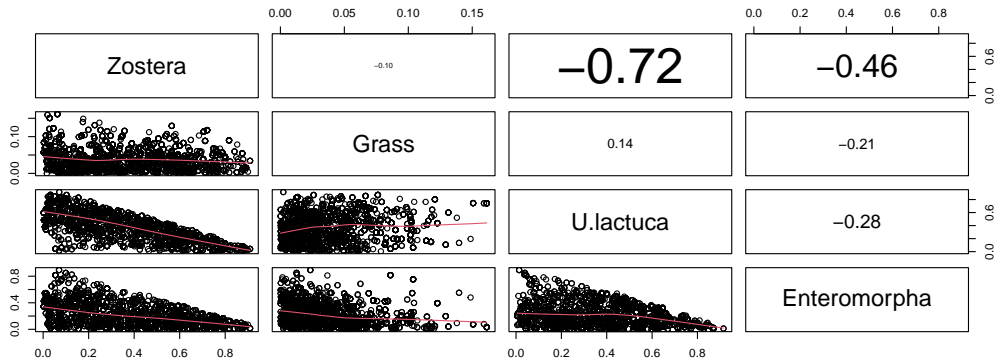

```
head(model_run$BUGSoutput$sims.matrix,4)
```

```
##      deviance      p[1]      p[2]      p[3]      p[4]      sigma
## [1,] 38.24013 0.2931735 0.037865208 0.6128807 0.05608053 2.666854
## [2,] 29.94426 0.2925945 0.049061414 0.4754383 0.18290585 1.237191
## [3,] 29.19475 0.3280195 0.051608762 0.4583445 0.16202724 1.385694
## [4,] 29.35735 0.5883123 0.004139584 0.1634236 0.24412454 1.037509
```

- ▶ The key implication of this is that, aside from exploring the *marginal* posterior distributions (with means, sds, etc) we can explore the *joint* uncertainty of the dietary proportions

A joint plot of the posterior dietary proportions

```
out_2 = model_run$BUGSoutput$sims.list$p  
colnames(out_2) = geese_data_day1$source_names  
pairs(out_2, lower.panel = panel.smooth,  
       upper.panel = panel.cor)
```

Trophic enrichment factors and concentration dependence

- ▶ Trophic enrichment factors (c) and concentration dependence (q) represent adjustments to the source values to account for various measurement effects
- ▶ We can include them by expanding the likelihood:

$$y_i \sim N \left(\frac{\sum_{k=1}^K p_k q_k (s_k + c_k)}{\sum_{k=1}^K p_k q_k}, \sigma^2 \right)$$

- ▶ The extra part on the denominator is needed so that the dietary proportions still sum to 1
- ▶ The prior for c_k comes from external data and are given normal distributions like the source values
- ▶ In SIAR/simmr the concentration dependencies must be less than 1 (given as proportions) and are treated as fixed

Including TEFs and CD - JAGS model

```
model_code = '  
model {  
  for(i in 1:N) {  
    y[i] ~ dnorm(inprod(p*q,s+c)/inprod(p,q),sigma^-2)  
  }  
  p ~ ddirch(alpha)  
  for(k in 1:K) {  
    s[k] ~ dnorm(s_mean[k],s_sd[k]^-2)  
    c[k] ~ dnorm(c_mean[k],c_sd[k]^-2)  
  }  
  sigma ~ dunif(0,100)  
}  
,  
data=with(geese_data_day1,  
  list(y=mixtures[,1], s_mean=source_means[,1],  
        s_sd=source_sds[,1], c_mean = correction_means[,1],  
        c_sd = correction_sds[,1], q = concentration_means[,1],  
        N = nrow(mixtures),K=nrow(source_means),  
        alpha=rep(1,length(source_names))))  
model_run = jags(data = data
```

Notes on the TEF and CD model

- ▶ If you run this, you'll find that convergence isn't quite as neat and it starts to get a bit slower
- ▶ Although it's a nuisance parameter, saving `sigma` is often a good idea because a large value indicates a poorly fitting model (usually also seen in the iso-space plot)
- ▶ The model will also create posterior distributions for `s` and `c`, though these are usually pretty similar to the prior, as there isn't much information about their values in the data

Adding extra isotopes

- ▶ If we have extra isotopes we can just repeat the likelihood multiple times, once for each value of the isotope. Only the dietary proportions are 'shared' between the isotopes
- ▶ Now write y_{ij} as the consumer values for observation i on *isotope* j , where $j = 1, \dots, J$
- ▶ We now have source values s_{jk} , TEF values c_{jk} , concentration dependencies q_{jk} , and each isotope has its own residual standard deviation σ_j
- ▶ The likelihood is now:

$$y_{ij} \sim N \left(\frac{\sum_{k=1}^K p_k q_{jk} (s_{jk} + c_{jk})}{\sum_{k=1}^K p_k q_{jk}}, \sigma_j^2 \right)$$

Richer source sampling

- ▶ The model we've been fitting up to now assumes that all individuals sample the same source value s_{kj} for each source and isotope. This is unrealistic
- ▶ A better model has each individual sampling a different source value from the source prior distribution, i.e. we now have s_{ikj}
- ▶ The JAGS code becomes:

```
for(k in 1:K) {  
  for(i in 1:N) {  
    for(j in 1:J) {  
      s[i,k,j] ~ dnorm(s_mean[k,j], s_sd[k,j]^2)  
    }  
  }  
}
```

- ▶ We can do the same with the trophic enrichment factors
- ▶ In fact with a bit of clever maths we can remove (*marginalise over*) the s_{ik} values to get a simpler model with fewer parameters.

The full simmr/SIAR model

- ▶ Using the trick mentioned on the last slide, we end up with a full model which looks like this:

$$y_{ij} \sim N \left(\frac{\sum_{k=1}^K p_k q_{jk} (\mu_{s,jk} + \mu_{c,jk})}{\sum_{k=1}^K p_k q_{jk}}, \frac{\sum_{k=1}^K p_k^2 q_{jk}^2 (\sigma_{s,jk}^2 + \sigma_{c,jk}^2)}{(\sum_{k=1}^K p_k q_{jk})^2} + \sigma_j^2 \right)$$

- ▶ This model has a more complicated likelihood, but removes the extra s and c parameters

Full SIAR model: JAGS code

```
model_code = '  
model {  
  for (i in 1:N) {  
    for (j in 1:J) {  
      y[i,j] ~ dnorm(inprod(p*q[,j], s_mean[,j]+c_mean[,j]) /  
        inprod(p,q[,j]), var_y[j]^-1)  
    }  
  }  
  p ~ ddirch(alpha)  
  for(j in 1:J) {  
    var_y[j] <- inprod(pow(p*q[,j],2),s_sd[,j]^2+c_sd[,j]^2)/pow(inprod(p,q[,j]),2)  
      + pow(sigma[j],2)  
  }  
  for(j in 1:J) { sigma[j] ~ dunif(0,100) }  
}  
'
```

Full simmr/SIAR model: R code

```
data=with(geese_data_day1,  
  list(y=mixtures,s_mean=source_means,  
    s_sd=source_sds,  
    c_mean=correction_means,c_sd=correction_sds,  
    q=concentration_means,N=nrow(mixtures),  
    J=ncol(mixtures),alpha=rep(1,length(source_names))))  
model_run = jags(data = data,  
  parameters.to.save = c("p", "sigma"),  
  model.file = textConnection(model_code),  
  DIC = FALSE)
```

Summary of posterior dietary proportions

```
out_2 = model_run$BUGSoutput$sims.matrix
colnames(out_2) = c(geese_data_day1$source_names, 'SD1', 'SD2')
t(round(apply(out_2,2,quantile,probs=c(0.025,0.5,0.975)),2))
```

##	2.5%	50%	97.5%
## Zostera	0.43	0.61	0.80
## Grass	0.03	0.07	0.12
## U.lactuca	0.01	0.14	0.35
## Enteromorpha	0.01	0.15	0.46
## SD1	0.05	0.86	2.45
## SD2	0.02	0.36	1.40

Some of these proportions are quite imprecise: perhaps see better with matrix plot?

Running SIAR/simmr

- ▶ The SIAR/simmr R packages run exactly this model with a few extra tweaks
- ▶ SIAR contained a slightly optimised algorithm as JAGS used to get a bit stuck on harder data sets.
- ▶ SIAR allows for direct plotting of the data in isotope space and p -space (i.e. dietary proportion space - pairs plots)
- ▶ SIAR allows for changing the α values to put in proper prior information
- ▶ SIAR includes convergence checking
- ▶ But don't use that anymore! Instead...

simmr version

- ▶ `simmr` is a much more elegantly written version of SIAR with neater plots and many more features
- ▶ Four steps to run a `simmr` model
 1. Call `simmr_load` to load in the data
 2. Call `plot` to see the iso-space plot
 3. Call `simmr_mcmc` to run the model
 4. Check convergence using `summary`
 5. Call `plot` or `summary` to access the output
- ▶ `simmr` has further features to combine sources and to compare dietary proportions

simmr code

```
# Load
data("geese_data_day1")
simmr_in = with(geese_data_day1,
               simmr_load(mixtures = mixtures,
                          source_names = source_names,
                          source_means = source_means,
                          source_sds = source_sds,
                          correction_means = correction_means,
                          correction_sds = correction_sds,
                          concentration_means = concentration_means))

# Iso-space plot
plot(simmr_in)

# MCMC run
simmr_out = simmr_mcmc(simmr_in)

# Box-plots
plot(simmr_out, type = 'boxplot')
```

Summary

- ▶ The `simmr` and `SIAR` models are just complicated versions of linear regression
- ▶ The response is multivariate and the prior distributions on some of the parameters have to be constrained to sum to 1
- ▶ It used to be the case that `JAGS` was slow and couldn't run `SIMM`-type models. This is no longer true. You can fit much richer models in `JAGS` (and now `MixSIAR`) than with `SIAR/simmr`
- ▶ The `MixSIAR` is an order of complexity again as it uses ideas from generalised linear models to include covariates on the dietary proportions
